#### 1. Aim and field of application

Shiga toxins (Stx), synonymous with Verocytotoxins (VT), are a toxin family characterized by an elevated degree of diversity. The Stx family is divided into two branches, Stx1 and Stx2, based on their antigenic differences. The terms "Stx1" and "Stx2" were also used to describe the prototypic toxins first described in each branch. Many toxin variants have been described in either branch and it has been recommended to classify Stx family members based on phenotypic differences, biologic activity and hybridization properties (3).

Classification of Stx variants does not represent only a taxonomic exercise: some of the variants are clinically relevant in that they are produced by strains isolated from cases of haemolytic uremic syndrome (HUS) (1,2,5), while others are primarily associated with milder course of disease (2,5) or are probably not produced by *E. coli* strains causing human disease (6).

Different systems of nomenclature have been proposed and used for Stx variants and their coding genes (*stx*) (3). A consensus on a comprehensive proposal of nomenclature has been reached during the 7<sup>th</sup> International Symposium on VTEC held in Buenos Aires, Argentina, VTEC2009 and the nomenclature was presented in its final form at the 8<sup>th</sup> VTEC2012 Symposium in Amsterdam, The Netherlands. This sequence based nomenclature has been used to develop the protocol for detection and subtyping of *stx* genes and the scientific analysis and presentation has been published (7). In summary, there are three levels of designations:

- 1. **Types**: Toxin type 1 and 2.
- 2. **Subtypes**: Stx/Stx1a, Stx1c and Stx1d. The prototypic Stx (in *Shigella* spp.) and Stx1 are grouped within one new subtype, Stx/Stx1a. Stx2 toxins include two new subtypes, Stx2a (the prototypic Stx2 sequence) and Stx2b (including the previously named Stx2d variant), and the five existing subtypes i.e. Stx2c, Stx2d (activation potential implied by sequence), Stx2e, Stx2f and Stx2g from *Acinetobacter haemolyticus*, *Citrobacter freundii*, *Enterobacter cloacae*, *Escherichia albertii* (4) and *Escherichia coli*.
- 3. Variants: Variants include the subtype specific prototypic toxins or related toxins within a subtype (that differ by one or more amino acids from the prototype). The variants are designated by toxin subtype, O group of the host *E. coli* strain, followed by the strain name or number from which that toxin was described. (e.g. Stx1a-O157-EDL933 or Stx2c-O157-E32511). Nucleotide variants within a given Stx subtype are italicised e.g. *stx2c*-O157-E32511 is a nucleotide variant that encodes Stx2c-O157-E32511.

The present method concerns the identification of the three *stx1* subtypes and the seven *stx2* subtypes of Stx encoding (*stx*) genes of *E. coli* by conventional PCR amplification. It is intended for application on isolated STEC strains.

The *stx* gene subtypes that represent the target of this method are: *stx1*: *stx/stx1a*, *stx1c*, *stx1d stx2*: *stx2a*, *stx2b*, *stx2c*, *stx2d*, *stx2e*, *stx2f* and *stx2g*.

## 2. Procedure

## 1.1. Principle of the method

The method is based on PCR amplification of specific DNA regions from a template DNA, with oligonucleotides triggering the start of the PCR reaction.

The procedure includes a first phase of identification of the *stx* gene types (*stx1* and/or *stx2*) possessed by the strain under examination. The primers for this preliminary typing step are shown in **Table 1**. The second phase concerns the determination of the *stx* gene subtypes and is performed by specific PCR reactions, using primers designed on the basis of analyses of existing *stx* sequences (7). The method is composed of the following steps:

- Template preparation
- Setting up the PCR reaction
- Determination of the PCR results by agarose gel electrophoresis.

## 1.2. Template preparation

Isolated strains are streaked onto solid media (e.g. TSA) and incubated overnight.

A single bacterial colony is inoculated in beef broth or TSB and incubated overnight.

100  $\mu$ l of the overnight culture is added to 900  $\mu$ l Milli Q water in an Eppendorf tube and boiled or placed in a heating block at 100 °C for 15 minutes. Centrifuge at 18.000 g for five minutes at room temperature. Upon transfer to a clean tube, the supernatant is used directly for PCR and stored at - 18°C for further analyses.

# 1.3. Setting up the PCR reaction

**Standard PCR** in total volume of 20  $\mu$ l: 2.5  $\mu$ l H<sub>2</sub>O § 10  $\mu$ l Mastermix (HotStarTaq, Qiagen), 1.25  $\mu$ l of each of two primers (STOCK solution of primers is 5  $\mu$ M) § 5  $\mu$ l supernatant of boiled lysate (STOCK)

§ If three primers are used (as for *stx2a* subtyping or *stx2d* subtyping without primer stx2d-O55-R), H<sub>2</sub>O volume is reduced to 1.25  $\mu$ l; If four primers are used (subtyping with all *stx2d* primers or running of the *stx2* detection system)

If four primers are used (subtyping with all *stx2d* primers or running of the *stx2* detection system), H<sub>2</sub>O is NOT added!

**Triplex-PCR** for subtyping of *stx1* in total volume of 25  $\mu$ l:

12 µl Mastermix (HotStartTaq, Qiagen),

1 µl of each of the four primers for stx1c and stx1d (STOCK solution of primers is 5 µM)

2 µl of each of two primers for stx1a (STOCK solution of primers is 5 µM)

5 µl supernatant of boiled lysate (STOCK)

The thermo cycler conditions are: *stx1* and *stx2* detection with primers stx1-det-F1/ stx1-det-R1; F4/R1/F4-f/R1-e/f: 95°C for 15 min (HotStartTaq activation) 35 cycles of 94°C for 50 sec, 56° for 40 sec and 72°C for 60 sec, ending with 72°C for 3 min.

stx1 and stx2 subtyping – see Table 1:
95°C for 15 min (HotStartTaq activation)
35 cycles of 94°C for 50 sec, 64-66°C (please see the Note on the design of primers and Table 1) for 40 sec and 72°C for 60 sec, ending with 72°C for 3 min.

PCR amplicons can be stored at 4°C until loading on agarose gel.

In each PCR assay, a positive and a negative control must be included. The positive controls are DNA templates obtained from *E. coli* strains harbouring the different *stx* subtypes that are the object of the present method (*stx1a*, *stx1c*, *stx1d*, *stx2a*, *stx2b*, *stx2c*, *stx2d*, *stx2e*, *stx2f* and *stx2g* – reference strains listed in **Table 4**), and the negative control is constituted by a sample without template added.

#### 1.4. Agarose gel electrophoresis

Prepare agarose gel in 1X Tris/Borate/EDTA (TBE) or Tris/Acetate/EDTA (TAE). Each well of the gel is loaded with 10  $\mu$ l of each PCR product added with loading dye at 1X final concentration. Run the samples in 1X running buffer (TBE or TAE) in constant voltage (100 V). Use a molecular weight marker suitable for assignment of the correct molecular weights to the amplicons produced (**Table 1**). Make sure that the bands produced by the reference strains match exactly the expected molecular weight.

Add ethidium bromide to the agarose gel to a final concentration of  $0.5 \ \mu g/ml$  before pouring it in the electrophoresis gel cast. Ethidium bromide is a DNA intercalating agent commonly used as a nucleic acid stain in molecular biology laboratories. When exposed to ultraviolet light, it will fluoresce with a red-orange colour. Alternatively, the agarose gel can be stained after electrophoresis in a 0.5  $\mu$ g/ml ethidium bromide aqueous solution.

#### 1.5. Safety and protection devices

Some STEC strains can infect human beings at a very low infectious dose and can cause severe disease. Laboratory acquired infections have been reported. Therefore, working with STEC requires good laboratory practices and the use of protection devices.

Ethidium bromide is a mutagen and toxic agent; therefore it should be used in compliance with the safety sheet provided and with protection devices (lab-coats and latex gloves). The UV light may cause damage to eyes so it is mandatory the use of plexiglas shields and protective glasses.

#### 1.6. Reference strains

STEC strains harbouring the different *stx* subtypes are listed in **Table 4** and should be used as positive controls – see **Figure 2** illustrating *stx2a*, *stx2b*, *stx2c*, *stx2d*, *stx2e*, *stx2f* and *stx2g* positive strains. A complete set of strains harbouring the genes encoding all *stx* subtypes (for a total of ten isolates) are provided by the WHO Collaborating Centre for Reference and Research on *Escherichia* and *Klebsiella*, The control templates can be prepared in advance as described for the test strains and stored at -20°C for eight months.

**Table 1**. List of primers to be used for *stx* genes detection and subtyping. PCR conditions are described in the text below. Annealing temperatures are 56°C for sequencing and detection, and 64-66°C for subtyping of *stx/stx1* or *stx2*. Especially, the resolution of *stx2a*, *stx2c* and *stx2d* may require individual calibration of thermocyclers; see note below <sup>a)</sup>

Wobble bases are shown in bold.

§ These primers will also detect Shiga toxin genes from Shigella dysenteriae type 1 and Shigella sonnei.

\* Triplex PCR for *stx1* subtyping: 1  $\mu$ l of each of the four primers for *stx1c* and *stx1d* (stock solution of primers is 5  $\mu$ M)

2 µl of each of two primers for *stx1a* (stock solution of primers is 5 µM). See Figure 1 for gel picture of fragment sizes.

\*\* One additional primer has been designed to specifically detect the stx2d-O55-5905 variant:

| Primer      | Sequence $(5^{\circ} - 3^{\circ})$ | Position  | Amplicon size (bp) |
|-------------|------------------------------------|-----------|--------------------|
| stx2d-O55-R | TCAACCGAGCACTTTGCAGTAG             | 1140-1161 | 235                |

All three reverse primers in the same reaction will result in amplicons of 179bp with 9 *stx2d* variants, 235bp with variant stx2d-O55-5905, 280bp with 5 *stx2d* variants, and finally two amplicons of 179bp and 280bp with variant stx2d-O73-C165-02.

Gradient testing by SSI on an Eppendorf thermocycler has indicated that the annealing temperatures for stx1 triplex PCR primers should be higher than 62.4 as shown in **Table 2**. As this may vary between thermocyclers we suggest that the annealing temperature is raised to 64°C or higher depending on the thermocycler.

**Table 2**. Maximum annealing temperatures for *stx1* subtyping in °C:

Clear bands are seen at annealing temperatures shown in bold.

Annealing temperatures for cross reacting bands between *stx1a*, *stx1* and *stx1d* are shown in [].

| Forward primer is <b>F1</b> in all cases; | stx1a | stx1c | stx1d  |
|-------------------------------------------|-------|-------|--------|
| Optional reverse <i>stx1c</i> primers     |       |       |        |
| <b>R1 &amp; R2</b> are shown              |       |       |        |
| stx1a                                     | >66.0 | None  | [56.8] |
| stx1c                                     | None  | >66.0 | [59.5] |
| stx1                                      | None  | None  | >66.0  |

One gradient was tested:

54.9 – 66.0°C in 12 wells: 54.9°C- 55.1°C- 55.8°C- 56.8°C- 58.1°C- 59.5°C- 61.0°C- 62.4°C- 63.7°C- 64.8°C - 65.6°C – 66.0°C Thermocycler: Eppendorf.

**Conclusion**: Unwanted cross-reactions with control strains for stx1a, stx1c and stx1d can be eliminated at annealing temperature higher than 59.5°C. Recommended annealing temperature is 64°C. Should you observe two stx1 subtypes in the same strain the annealing temperature should be raised to 66°C.

<sup>a</sup> NOTE on the design of primers: Stx2a, Stx2c and Stx2d are very closely related and the design of primers has been quite difficult! We have identified thirty stx2a, twenty-four stx2c and twenty-six stx2d nucleotide variants. The primers that we have designed should be specific for each of their respective variants. However, as we have not tested all these many variants, our design is based on the fact that the primers match all the desired sequences. Furthermore, we have noted that cross-reactions occur and are seen as ghost bands – especially between stx2c and stx2d positive strains. This is illustrated in **Figure 3**. Thus, only very clearly positive bands should be interpreted as indicative of presence of that specific subtype.

Independent laboratories have indicated that they have had difficulties with the three control strains for stx2a, stx2c and stx2d where they have seen unwanted cross-reactions. On some thermocyclers this problem may be resolved by careful calibration of individual brands of thermocyclers by testing annealing temperatures from 64-66°C on the test panel of reference strains.

In our hands, an additional PCR using the stx2d primers were run at an annealing temperature of 66°C. False positive stx2c fragments disappeared and true stx2d positive fragments persisted at this annealing temperature.

Gradient testing by ISS and SSI on different thermocyclers has indicated that the maximum annealing temperatures may vary a little in different laboratories as shown in the below **Table 3**.

Table 3. Maximum annealing temperatures for *stx2* subtyping in °C:

Clear bands are seen at annealing temperatures shown italicised top is laboratory 1 and bold is laboratory 2; weak visible bands in brackets (). Annealing temperatures for cross reacting bands between stx2a, stx2c and stx2d are shown in [].

|       | stx2a       | stx2b | stx2c       | stx2d       | stx2e | stx2f  | stx2g |

|       | [<58]       |       | 64.4-65.0   | [60.5]      |       |        |       |
|       | *           |       | (65.6-66.0) | *           |       |        |       |
| stx2d |             |       |             | 63          |       |        |       |
|       | [<58]       |       | [60.5]      | 65.0-65.6   |       |        |       |
|       | *           |       | *           | (66.9-67.0) |       |        |       |
| stx2e |             |       |             |             | >67   |        |       |
| stx2f |             |       |             |             |       | 68.1   |       |
|       |             |       |             |             |       | (69.5) |       |
| stx2g |             |       |             |             |       |        | >67   |

\* One test laboratory has seen cross-reactions at  $62^{\circ}$ C using a Biometra cycler. These were resolved using an annealing temperature at  $64^{\circ}$ C.

Three different gradients were tested in two laboratories:

62 – 69.8°C in 10 wells: 62°C- 63°C- 64.7°C- 65.6°C- 66.4°C- 67.2°C- 68.1°C- 68.9°C- 69.4°C- 69.8°C

58 - 67°C in 10 wells (temperature difference between wells = 1 °C)

58 - 72°C in 12 wells (temperature difference between wells ~ 1.3 °C)

Thermocyclers: Perkin Elmer 9700, Euroclone PeQ Star, Biometra cycler and Eppendorf.

**Conclusion**: In order to eliminate unwanted cross-reactions with control strains for stx2a, stx2c and stx2d an annealing temperature 64-66°C is recommended. This should also work for all the other stx2 subtypes: stx2b, stx2e, stx2f and stx2g.

Note on the choice of Taq polymerase: During our test phase, we have noted that the (conventional) PCR's are Taq dependent and therefore, the protocol should be followed exactly as described using the Qiagen HotStarTaq Master Mix Kit. HotStarTaq Master Mix Kit comes in three different "sizes" 250U, 1000U and 2500U. Cat.No.s 203443, 203445 and 203446. It's a pre-made mastermix. You just add template, primers and water. One participant has tested the protocol with Go Taq Green (Promega) and FastStart High Fidelity Taq (Roche) at annealing temperature at

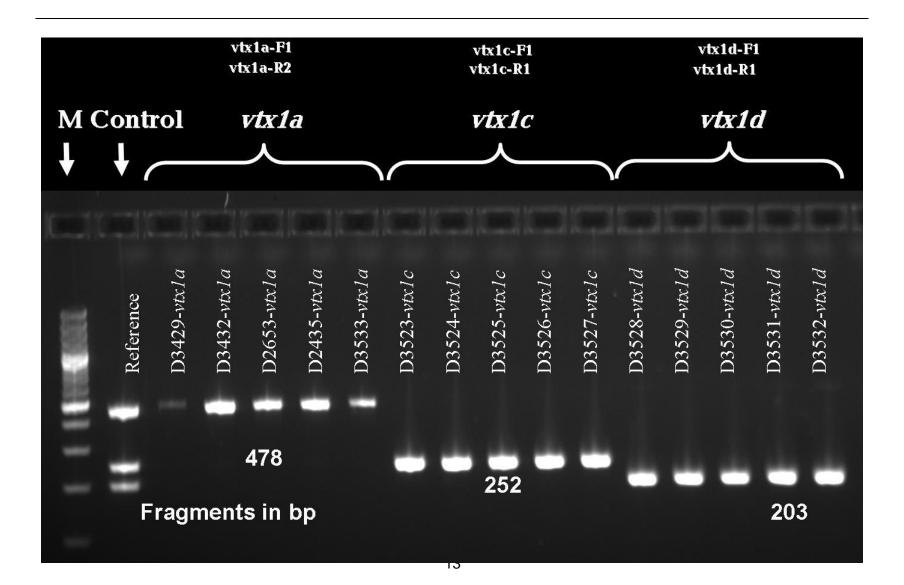

64°C with unsatisfactory results. We have no commercial interest in Qiagen and you are of course welcome to test other Taq polymerases – but we recommend that you

do this after you have validated the control strains using the Qiagen HotStart Master Mix Kit.

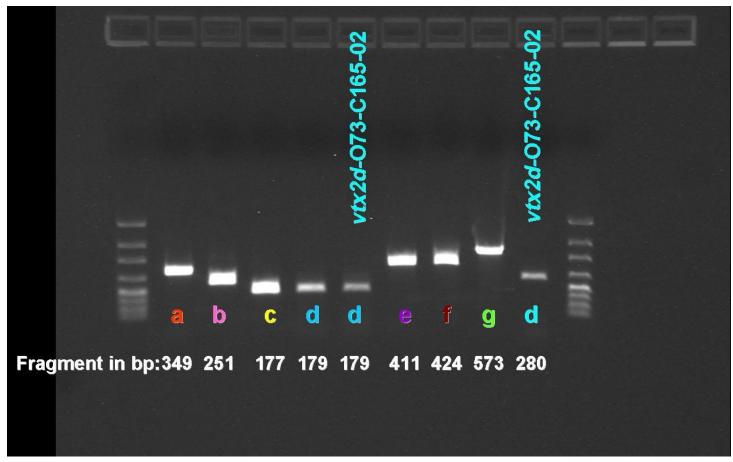

Figure 1. Gel picture illustrating five strains each of *stx1a*, *stx1c* (with reverse primer stx1c-R1) and *stx1d* positive strains.

**Figure 2**. Gel picture illustrating *stx2a*, *stx2b*, *stx2c*, *stx2d*, *stx2e*, *stx2f* and *stx2g* positive strains. D3435 (strain C165-02) can be positive with both reverse primers resulting in two bands of 179bp and/or 280bp respectively.

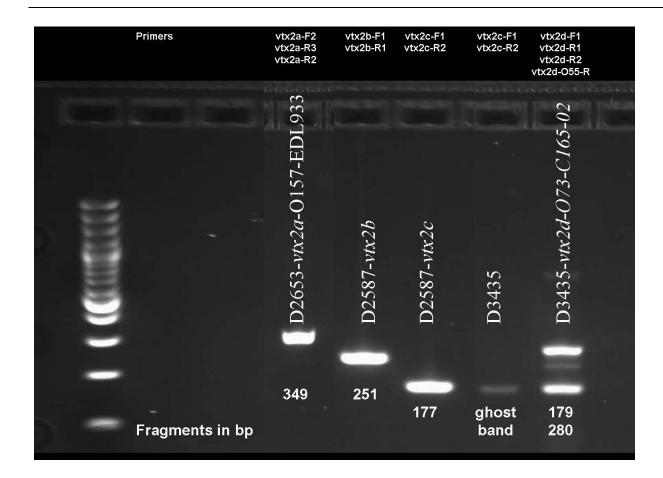

**Figure 3**. Gel picture illustrating *stx2a*, *stx2c* and *stx2d* positive strains.

D3435 (strain C165-02) is positive with both stx2d-R1 and stx2d-R2 resulting in two bands of 179bp and 280bp, respectively (last lane). Because of the high degree of similarity between stx2c and stx2d some stx2d positive strains (D3435) also give a weak stx2c ghost band. In order to distinguish between a ghost band and a true stx2c band compare with D2587 (strain 031), which is clearly positive for stx2c (and stx2b).
